

Description:

Write a function that takes an array of numbers (integers for the tests) and a target number. It should find two different items in the array that, when added together, give the target value. The indexes of these items should then be returned in a tuple / list (depending on your language) like so: (index1, index2).

For the purposes of this kata, some tests may have multiple answers; any valid solutions will be accepted.

The input will always be valid (numbers will be an array of length 2 or greater, and all of the items will be numbers; target will always be the sum of two different items from that array).

Based on: <https://leetcode.com/problems/two-sum/>

```
twoSum([1, 2, 3], 4) // returns [0, 2] or [2, 0]  
twoSum([3, 2, 4], 6) // returns [1, 2] or [2, 1]
```
