

Description:

The word `i18n` is a common abbreviation of `internationalization` in the developer community, used instead of typing the whole word and trying to spell it correctly. Similarly, `a11y` is an abbreviation of `accessibility`.

Write a function that takes a string and turns any and all "words" (see below) within that string of **length 4 or greater** into an abbreviation, following these rules:

- A "word" is a sequence of alphabetical characters. By this definition, any other character like a space or hyphen (eg. "elephant-ride") will split up a series of letters into two words (eg. "elephant" and "ride").
- The abbreviated version of the word should have the first letter, then the number of removed characters, then the last letter (eg. "elephant ride" => "e6t r2e").

Example

```
input: "elephant-rides are really fun!"
      ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
words (^):  "elephant" "rides" "are" "really" "fun"
            123456     123     1     1234     1
ignore short words:           X           X

abbreviate:  "e6t"      "r3s"  "are"  "r4y"   "fun"
all non-word characters (*) remain in place
            "_-"      " "  " "  " "  " "  "!"

output: "e6t-r3s are r4y fun!"
```
